

You've got the momentum, so let's keep the pace high. Since you've already mastered the "catch and clean" phase with webhooks, here is the complete **Week 6: The Multi-Step Engine** challenge.

This week is about building "The Brain" of an automation—moving from simple A-to-B transfers to complex logic that makes decisions based on the data it receives.

This involves using the Router to create different paths for different customer interests—like separating a "Senator Wear" lead from a "Footwear" lead so they each get a unique, high-end experience.

You've got the technical skills and the official certification to back it up, Otuto. The "Black Box" is open, and you're the one in control of the wires now.

Question 1: The "Search-Before-Create" (Deduplication)

In a real CRM like HubSpot, you never want to create duplicate contacts. It ruins the data and confuses the sales team.

- **The Task:** After your Webhook catches a lead, you need to add a "Search" module.
- **The Logic:** How do you configure a search to check if a contact's email already exists in HubSpot?
- **The Follow-up:** If the search finds someone, which module do you use to update them instead of creating a new one?

Question 2: The Multi-Path Router (The Decision Maker)

A business often has different "fulfillment" paths. For example, a "Senator Wear" order needs a tailor, but a "Jean Footwear" order needs a cobbler.

- **The Task:** Add a **Router** to your scenario.
- **The Logic:** Set up three distinct branches:
 1. **Branch 1:** Interest is "Senator Wear" → Send to a "Tailoring" Slack channel.
 2. **Branch 2:** Interest is "Jean Footwear" → Send to a "Footwear" Slack channel.
 3. **Branch 3:** Interest is "Other" (The fallback) → Create a generic task in a project management tool.
- **The Question:** What is the technical term for the branch that catches everything that doesn't fit the first two rules?

Question 3: The "Fail-Safe" (Basic Error Handling)

Technical operations aren't just about building things that work; they are about building things that don't break when the internet hiccups.

- **The Scenario:** You are sending data to an external API, but the API is temporarily down (a 500 error).
- **The Task:** Right-click a module in Make.com. You will see "Add error handler."
- **The Question:** If you want the automation to wait 15 minutes and try again automatically instead of just stopping, which "Error Handler" directive do you use?

Question 4: Data Aggregation (The "Wrap Up")

Sometimes, an automation creates many small pieces of data (like a list of items in an order) that need to be sent in **one single** email at the end.

- **The Task:** Look for the "Array Aggregator" module.
- **The Logic:** If you have 5 separate "Line Items" from an order, how does the **Aggregator** change the way that data looks before it hits the "Send Email" module?

How to Tackle These

You have the **Revenue Operations** strategic foundation to understand the "Why". Now, use your **Make.com** and **Postman** skills to solve the "How."

You can build these out in one "Super Scenario" and send a screenshot, or explain the logic for each. Which part of the "Engine" are you going to wire up first?
